Cost Analysis

- Direct Costs - directly related to designing, testing, building, and operating the system
- Indirect Costs - required to do business, but not directly associated with development or operations
  - Management
  - Profit
  - Non-operational facilities
  - Overhead

Direct Cost Breakdown

- Non-recurring costs - only incurred once in program, such as design

- Recurring costs - reoccur throughout the life of the program
  - Per vehicle
  - Per flight
  - Per year

Cost Estimation and Engineering Economics
ENAE 791 - Launch and Entry Vehicle Design

Nonrecurring Cost Sources

- Research
- Design
- Development
- Test and evaluation
- Facilities
- Tooling

UNIVERSITY OF
MARYLAND

Cost Estimation and Engineering Economics
ENAE 791 - Launch and Entry Vehicle Design

Recurring Cost Sources

- Vehicle manufacturing
- Mission planning
- Pre-flight preparation and check-out
- Flight operations
- Post-flight inspection and refurbishment
- Range costs
- Consumables (e.g., propellants)
- Training

Refurbishment

- Cost associated with maintenance and upkeep on reusable vehicles between flights

- Refurbishment fraction f_R - fraction of first unit production cost that is required for average post-flight refurbishment

  - Airliner: ~0.001%

  - Fighter jet: ~0.01%

  - X-15: 3%

  - Shuttle: 6-20%

- Major contributor to space flight costs

Vehicle-Level Cost Estimating Relations

$$C(\$M) = a\left[m_i\langle kg\rangle\right]^b$$

Spacecraft Type	Nonrecurring a	Nonrecurring b	1st unit production a	1st unit production b
Launch Vehicle Stage	8.662	0.55	0.2057	0.662
Manned Spacecraft	21.95	0.55	0.6906	0.662
Unmanned Planetary	13.89	0.55	1.071	0.662
Unmanned Earth Orbital	4.179	0.55	0.4747	0.662
Liquid Rocket Engine	34.97	0.55	0.1924	0.662
Scientific Instrument	2.235	0.50	0.3163	0.70

2008$ 2008$

Implications of CERs

- Launch Vehicles
  - Nonrecurring $42K-$182K/kg inert mass
  - 1st Unit $3600-$10.7K/kg inert mass
- Manned Spacecraft
  - Nonrecurring $119K-$1.56M/kg inert mass
  - 1st Unit $13K-$90K/kg inert mass

Costing Applied to Launch Vehicle Design

Optimization Approach	ΔV Distribution (m/sec)	Gross Mass (kg)	Inert Masses (kg)	NR Cost ($M99)
Minimize Gross Mass	4600 4600	134,800	2,937 <u>10,780</u> 13,721	576 <u>1177</u> 1753
Minimize Inert Mass	3356 5844	139,000	2,066 <u>11,123</u> 13,189	474 <u>1197</u> 1672
Minimize Nonrecurring Cost	2556 6644	147,000	1,666 <u>11,762</u> 13,428	421 <u>1235</u> 1656
Single Stage to Orbit	9200	226,400	18,115	1566

5000 kg payload, LOX/LH2 engines

Cost Estimation and Engineering Economics
ENAE 791 - Launch and Entry Vehicle Design

The Learning Curve

- The effort (time, cost, etc.) to perform a test decreases with repetition

- Doubling the production run results in consistent fractional reduction of effort

  - "80% learning curve" - 2nd unit costs 80% of 1st, 4th is 80% of 2nd, 8th is 80% of 4th...
  - $C_n = C_1 n^p$

  - Average cost:

$$\bar{C}_n \approx C_1 \frac{n^p}{1-p}$$

$$p = \frac{\log\left(\frac{C_2}{C_1}\right)}{\log(2)}$$

Cost and Learning Effects
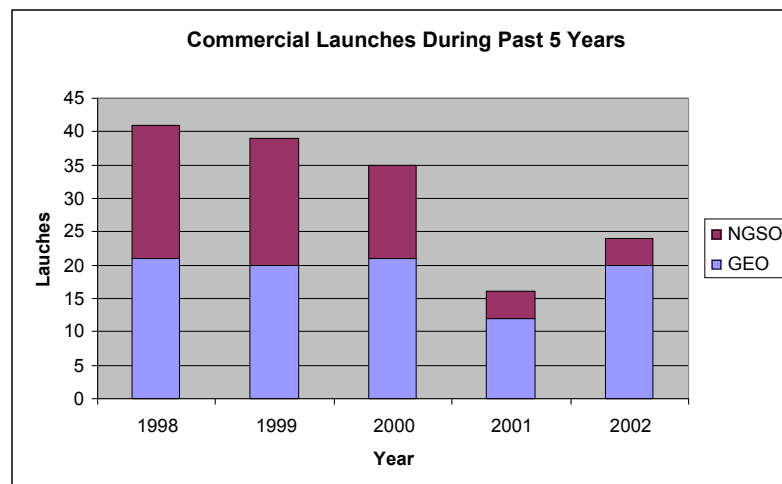

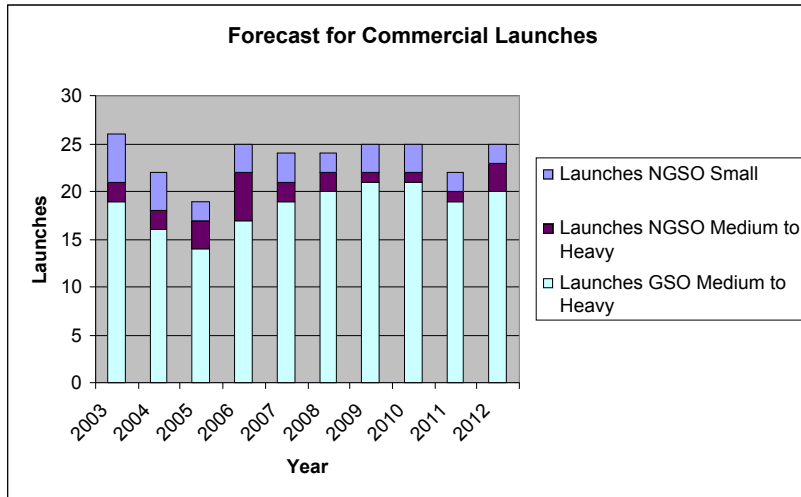

Total Program Payload Mass = 1,000,000 kg

Payload Mass per Flight (kg)

Legend:
- Nonrecurring Cost
- Recurring Cost
- Operations Costs
- Total Program Cost

Expendable/Reusable Trade Study

Total Market to Orbit=1,000,000 kg

ENAE 791 - Launch and Entry Vehicle Design

Cost Modeling

Forecast for Commercial Launches
- Launches NGSO Small
- Launches NGSO Medium to Heavy
- Launches GSO Medium to Heavy

Commercial Launches During Past 5 Years
- NGSO
- GEO

- At ~$100M/launch, worldwide annual launch revenue is ~$6-8 B

- Potential savings by cutting costs by factor of 2 is ~$3-4 B

- Given a 10 year development program and a 10% discount rate (government support), maximum feasible program cost for new vehicle is ~$2.5 B/yr

- At a 50% ROI (commercial), maximum yearly expenditure is ~$70 M

- Only economically feasible as a government program

- Budget caps reduced if launch costs don't drop as much (e.g., 75% of current launch costs gives annual NTE of $1.25 B)

- Incorporation of advanced technology is only justified insofar as it reduces launch costs

- *Design goal is effective, not efficient!!!*

Parametric Cost Analysis

- Preliminary model developed to bound problem, identify critical parameters

- Assumptions:
  - Total program launch mass 20,000 MT
  - Program lifetime 20 years
  - NASA SLVLC model for cost estimates
  - 80% learning curve
  - Vehicle modeled as LOX/LH2 SSTO (δ=0.08; I_{sp}=420 sec avg.)
Effect of Refurbishment Rate
Effect of Vehicle Lifetime
Effect of Total Launch Mass

Effect of Refurbishment Fraction
Costing Conclusions (to date)

- Primary cost drivers are refurbishment and mission operations costs
  - Keep flight rate *and* production rates high to take advantage of learning curve
  - Strong sensitivity to fleet size
- Prediction: effects will be *worse* with RLV
  - Smaller fleet sizes
  - Higher (inert mass)/(payload mass) ratios
  - Effects of vehicle losses on program resiliency
- Need to add cost discounting
- Bottom line: compare cost of airbreathing RLV vs. rocket RLV vs. expendable launch vehicle (*not* a foregone conclusion!)

Inflation

- As money supply and economy expand, buying power of money decreases

- A fixed sum of money is worth less from year to year

- "Real year dollars" - what specific year the money is quoted for (e.g., "$M2000")

- "Constant year dollars" - costing multiyear program based on buying power in single specified year (inflation added later)

Annual NASA Inflation Rates 1960-2020

Cost Estimation and Engineering Economics
ENAE 791 - Launch and Entry Vehicle Design

Cost Discounting

- Opportunity costs of money
- Analogous to compound interest at a bank
- **Not** the same thing as inflation
- Basic Definitions:
  - Net Present Value (NPV) - value of future sum today
  - Net Future Value (NFV) - value of sum today in the future
  - Discount Rate (r) - annual interest rate
- Provides a method of comparing costs across multiple years

Basic Equations of Cost Discounting

- Net Present Value (NPV)

$$C_i = C_{i+n}(1+r)^{-n}$$

- Net Future Value (NFV)

$$C_{i+n} = C_i(1+r)^n$$

- NPV of constant annual payments of R

$$C_i = R\frac{1-(1+r)^{-n}}{r}$$

- NFV of constant annual payments of R

$$C_{i+n} = R\frac{(1+r)^n - 1}{r}$$

Cost Discounting Example: Saturn V Costs

Year	$M2000	NPV (2000) (r=0.10)	NFV (2010) (r=0.10)
2001	3255.4	2959.4	7676.0
2002	4045.8	3343.6	8672.5
2003	4831.0	3629.6	9414.3

Internal Rate of Return

- Discount rate that produces breakeven

UNIVERSITY OF
MARYLAND
Effect of IRR Targets

- Investors generally require specific minimum values of IRR

- Have to increase revenue stream to achieve IRR

- Saturn V launch case:
  - 10% IRR $11,480/lb
  - 25% IRR $17,580/lb
  - 50% IRR $32,700/lb

- Venture capitalists general look for 70-100% IRR with 18-month payback
In-line SDLV Assumptions

- **$8.4B nonrecurring (published estimate)**

- **6 year development cycle**

- **$400M first unit production (shuttle parallel)**

- **10 units at 85% learning curve**

- **$285M average flight cost**

Unit	Cost ($M)	Unit	Cost ($M)
1	400	6	263
2	340	7	253
3	309	8	246
4	289	9	239
5	274	10	233

Head-to-Head Launch Comparison

2000	Nonrecurring cost ($M)	10,200
829	Average production cost per mission ($M)	429
1096	Average amortized cost per mission ($M)	1449
85	Total production run	10+10
432	NPV discounted cost per mission ($M)	878
Sensitivity to Monolithic Costing
$432M	**Baseline NPV discounted cost per mission**	**$878M**
$432M	**Development costs cut in half**	**$508M**
$432M	**Production costs cut in half**	**$809M**
$432M	**Production is free**	**$740M**
$432M	**All costs cut in half**	**$439M**
Cost Spreading Estimation

- Programs very seldom occur in a single funding year
- Costs are not constant from year to year
  - Low start-up costs
  - High costs during vehicle development and fabrication
  - Low end-of-life costs
- Costs are estimated using a beta function
- Calculation worksheet at http://cost.jsc.nasa.gov/beta.html

Beta Function for Cost Spreading

- Cumulative normalized cost function

$$C(\tau) = 10\tau^2(1-\tau)^2(A + B\tau) + \tau^4(5 - 4\tau)$$

where

- C = fraction of total program cost $(0 \leq C \leq 1)$
- τ = fraction of total program time $(0 \leq \tau \leq 1)$
- A and B = shape parameters $(0 \leq A+B \leq 1)$
- Can also define equivalent parameters c_f (location of maximum) and P (width of peak) $0 \leq P \leq 1$; $0.1875 \leq c_f \leq 0.8125$

$$c_f < 0.5 : A = \frac{(1-P)(c_f - 0.1875)}{0.625}; B = P\frac{c_f - 0.1875}{0.3125}$$

$$c_f \geq 0.5 : A = \frac{P(c_f - 0.8125) + (c_f - 0.1875)}{0.625}; B = P\frac{0.8125 - c_f}{0.3125}$$
Sample of Beta Function

Cost Fraction in Beta Function

Peakedness in Beta Function

Beta Curve Fit to Saturn V Data

$A=0.371; B=0.629$
